Hsp60/10 client vulnerability is selective across the full client network

Late–stage protein collapse is heterogeneous; highly collapsing clients show stronger network centrality, while RNA–protein discordance is not uniformly elevated.

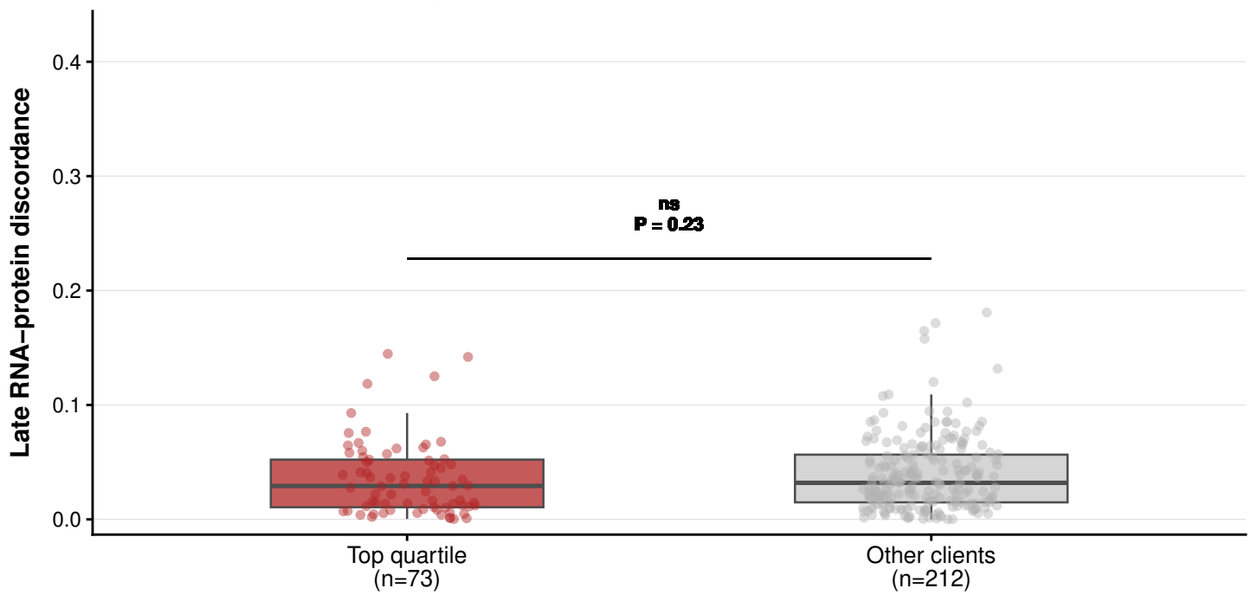

A. Collapse is heterogeneous across the Hsp60/10 client network

All detected Hsp60/10 clients are ranked by late–stage protein collapse; red marks the top quartile.

B. RNA–protein discordance

Discordance is not significantly higher in the top–collapse quartile.

C. Network centrality

Top–quartile collapsing clients occupy more central positions in the client network.
