

Hsp60/10 client vulnerability is preferentially coupled to Braak/tau pathology

Covariate-adjusted Braak/tau and CERAD/amyloid associations were modeled separately across detected Hsp60/10 clients.

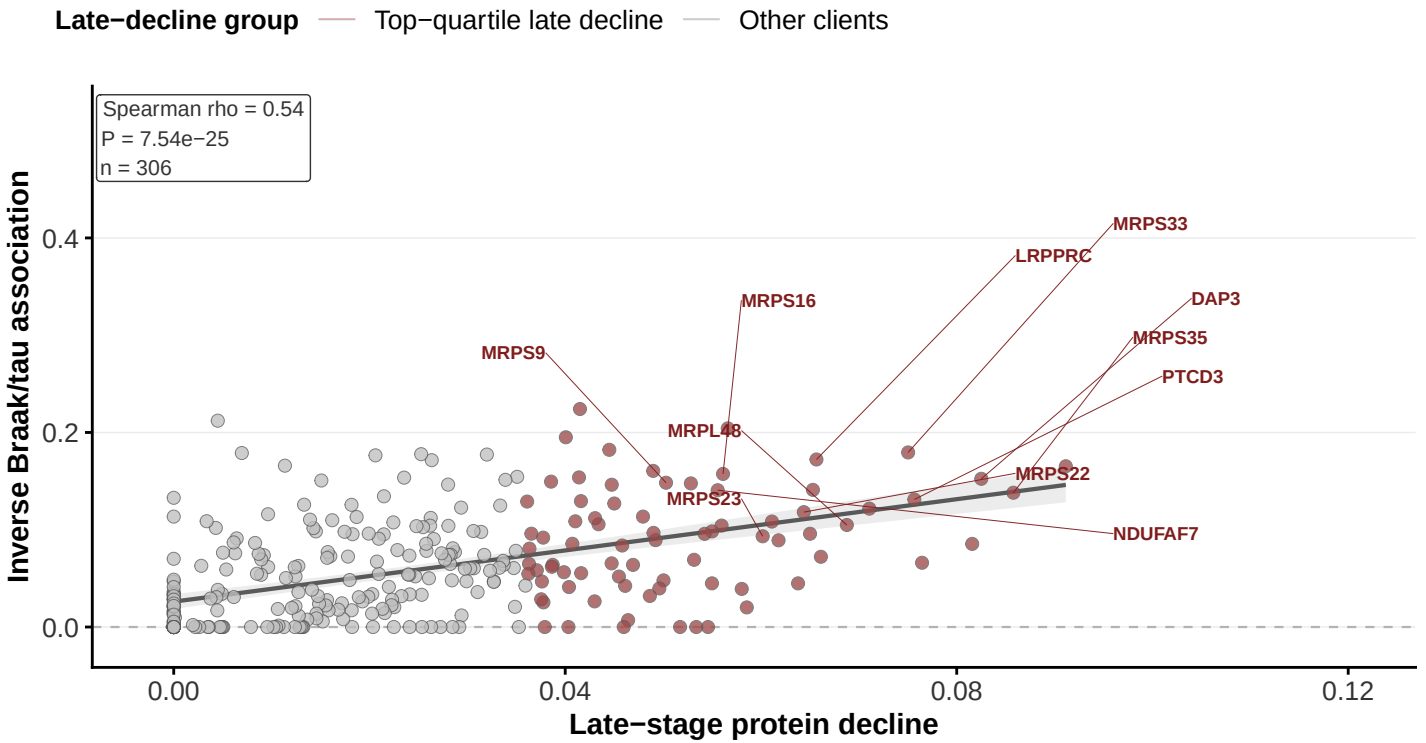

A. Inverse pathology coupling is stronger for Braak/tau than CERAD/amyloid

Covariate-adjusted Braak/tau and CERAD/amyloid associations were modeled separately for each client.

B. Late-stage decline is continuously associated with inverse Braak/tau coupling

Greater late-stage protein decline aligns with stronger direct inverse Braak association.

C. Braak/tau coupling exceeds CERAD/amyloid coupling across the client network

Positive values indicate stronger inverse Braak/tau coupling than inverse CERAD/amyloid coupling for the same client.
